

Specification Page 2 - Amended with Underlining and
Strikethroughs

by integrating a fusible sheet and fusible fibers.

In the cleaning devices according to these inventions, a fusible material is selected and used for both the fibers and the base material sheet. As a process for producing these cleaning devices, there is adopted a heat-sealing system in which the fibers and base material sheet are integrally bonded together through melting by heat.

Disclosure of the Invention

While ~~advantageous in~~ there is an advantage that it ~~allows it is possible to conduct an~~ operation in a small number of steps, in the above-described conventional technique, ~~in which for bonding integrally~~ the fibers and the base material sheet are ~~integrally bonded together~~ by heat sealing, ~~has~~ the following problems occur.

First, ~~while the~~ even though only a small number of ~~process steps is required is small in the above stated~~ system, the ~~above~~ system requires still a long time for sufficient heating ~~time for~~ of the fibers and the base material sheet to be completely heat-sealed, resulting in the long processing operating time and high processing cost therefor.

Second, when the fibers and the sheet are formed of different materials, it is rather difficult to integrate them uniformly and reliably by heat sealing. That is, the melting temperatures of the fibers and the sheet are not always the same, ~~so that~~ therefore, in order to bond them together to a sufficient degree by the heat sealing, it is necessary to perform heating at a sufficiently high temperature also on the material with a higher melting temperature. Thus, ~~one material~~ the

Specification Page 4 - Amended with Underlining and
Strikethroughs

Thus, when, in particular, the base material is a thin sheet member, a convex press mark is likely to be generated on the sheet upper surface on the side opposite to the surface (lower surface) to which the fiber are bonded. When such a press mark is generated, not only the outward appearance of the product but also the smoothness of the sheet upper surface is impaired. Thus, when the conventional heat sealing system is adopted, there are involved problems, such as a deterioration in the ~~machinability~~ workability of the sheet upper surface, and a deterioration in the dust collecting capacity when the sheet upper surface is used as the cleaning sheet. Further, in the case of such heat sealing system, there is a fear of the surface to be cleaned being damaged during cleaning by the thermally ~~set~~ hardened heat-sealed portion.

In view of these problems, it is an object of the present invention to provide a cleaning device which is superior in dust collecting capacity and which allows material selection from a wide range in terms of the fibers and the base material sheet forming the same and can be produced in a short processing time while preventing thermal deterioration in and thermal hardening ~~setting~~ of

the material, and a process for producing the same.

The cleaning device of the present invention is characterized by comprising a fiber bundle composed of a large number of fibers bonded to a base material sheet by means of an adhesive. Thus, even when either the fibers or the base material sheet or both materials

Specification Page 5 - Amended with Underlining and
Strikethroughs

are devoid of fusibility, it is possible to obtain the cleaning device of the present invention, so that material selection is possible from a wider range than in the prior art. Thus, according to the requisite specifications, such as the configuration and durability of the base material, and recycling property, it is possible to freely make material selection even from materials with no fusibility.

Further, a bonding system using an adhesive is adopted, so that even when the fibers and the base sheet are formed of different materials, it is possible to effect integral bonding of these members reliably and uniformly. Further, since it is possible to select the hardness of the adhesive, if a soft adhesive is adopted, there is no fear of thermal hardening ~~setting~~ of the bonding portion or damaging of the surface to be cleaned as in the case of the heat sealing system. Further, by using a hot melt type adhesive, it is possible to effect bonding by solely heating and cooling the materials to a relatively low temperature, thereby substantially reducing the processing time and the processing cost.

In the case of the conventional heat sealing system, the bonding portion, which is generally of a narrow and

linear configuration, undergoes concentrated heating and pressurization in order to melt the materials to be heat-sealed to a sufficient degree and to effect heat sealing without involving any spots. Thus, in the case of the conventional heat sealing system, in particular, in which the base

Specification Page 6 - Amended with Underlining and
Strikethroughs

material is a thin-walled sheet and in which a large number of filaments are placed on the base material for integral heat pressing, a convex press mark is generated on the upper surface side of the base material sheet, resulting in various problems. In contrast, in the system of the present invention, in which the base material sheet and a fiber bundle of filaments are bonded together by means of an adhesive, it is possible to avoid local application of load, so that the upper surface material of the base material sheet advantageously suffers little damage regardless of the thickness thereof.

In the cleaning device of the present invention, the bristle-like-member-less portion of the brush-like sheet with a plurality of bristle-like members may be integrally bonded to the fiber bundle and the base material sheet by means of an adhesive. In this case, through a combination of the brush sheet and the fiber bundle, it is possible to efficiently scrape out and collect dust. Further, of the brush sheet, the bristle-like-member-less portion thereof is bonded to the base material sheet or the fiber bundle, so that integration therewith can be reliably effected with a small amount of adhesive.

Further, the fiber bundle may be a filament bundling body provided with a bundling portion connecting filaments aligned in the fiber direction with each other. Due to this arrangement, even when the cleaning device is repeatedly used, there is no fear of

Specification Page 8 - Amended with Underlining and
Strikethroughs

The bundling portion connecting filaments to each other may be provided linearly in a direction crossing the filaments.

The bonding portion between the filament bundling body connecting the filaments to each other and the base material sheet may be provided linearly or in the form of a plurality of spots.

The filament bundling body may be bonded to the base material sheet at the ~~by~~ a bonding portion of a predetermined width located at a substantially central position with respect to the fiber direction.

The adhesive used is preferably a hot melt type adhesive and may contain a coloring agent.

The base material sheet may have a handle mounting portion.

The fiber bundle may be provided on both the upper and lower sides of the base material sheet.

A process for producing a cleaning device according to the present invention includes: aligning a large number of filaments with fusibility in fiber direction; fusing together the substantially central portions of the filaments by fusing means to form a filament bundling body;

applying an adhesive to the position corresponding to ef a bonding portion between the filament bundling body and a base material sheet; stacking together the filament bundling body and the base material sheet; and bonding together the filament bundling body and the base material sheet at the position of the bonding portion.

Specification Page 9 - Amended with Underlining and Strikethroughs

Further, according to the present invention, a cleaning device can be manufactured by a method including: aligning a large number of filaments with fusibility in fiber direction; fusing together the substantially central portions of the filaments by fusing means to form a filament bundling body; applying a hot melt type adhesive to the position corresponding to ~~of~~ a bonding portion between the filament bundling body and a base material sheet; stacking together the filament bundling body and the base material sheet; heating the filament bundling body and the base material sheet to a temperature not lower than the melting temperature of the hot melt type adhesive by a press heater and pressurizing the filament bundling body and the base material; and heating the position of the bonding portion to a temperature not lower than the fusion temperature of the filaments by a hot cutter and pressurizing the position of the bonding portion to bond together the filament bundling body and the base material sheet at the position of the bonding portion.

Best Mode for carrying out the Invention

In the following, embodiments of the present invention will be described specifically with reference to the drawings. The present invention, however, is not restricted to the following

embodiments, for example, in terms of the outer configuration of the fiber bundle and the base material sheet, the application configuration and application position of the adhesive, the position where the fibers are bundled with each other, and the presence and the configuration of the handle. Fig. 1 is a perspective view of a cleaning device according to a first embodiment of the present invention.

In the drawing, reference numeral 1 indicates a cleaning device. The cleaning device 1 has a handle mounting portion 2. Support bars 5 of a handle 4 are inserted into insertion holes 3 of the handle mounting portion 2; whereby the cleaning device can be used as a hand mop. The cleaning device 1 of the present invention is formed by integrally bonding a base material sheet 6 to a fiber bundle 7 consisting of a large number of fibers bundled together in a sheet-like form. Further, as shown in Fig. 2, in the cleaning device 1 of this embodiment, a brush sheet 9 with bristle-like members 8 is bonded to the fiber bundle 7 and integrated therewith. Regarding the order in which the fiber bundle 7 and the brush sheet 9 are stacked, it does not matter which of them comes on the

upper side and is bonded to the base material sheet 6. In this embodiment shown, the fiber bundle 7 is bonded between the base material sheet 6 and the brush sheet 9 and integrated therewith. In the present invention, the fiber bundle 7 formed of fibers and the bristle-like member 8 of the brush sheet 9 will be generally referred to as a main cleaning

Specification Page 12 - Amended with Underlining and
Strikethroughs

portion for performing dust collection.

The base material sheet 6 is a thin-walled base of the cleaning device. The base material sheet 6 supports the main cleaning portion and is itself capable of being flexibly deformed according to the configuration of the surface to be cleaned; it is a member having a function by which a satisfactory dust collection performance can be obtained for the cleaning device. While there are no particular limitations regarding its thickness and configuration, it is generally a sheet having a thickness of 1 mm or less and a circular, oblong, elliptical, or rectangular outer configuration. Regarding the material of the base material sheet 6, there are no particular limitations as long as it allows the main cleaning portion to be suitably bonded thereto by an adhesive. For example, a sheet of paper, synthetic resin sheet, or non-woven fabric sheet is used as the base material sheet 6. Of these, from the viewpoint of lightness, strength, durability, and adhesion property, non-woven fabric is suitably used. While it is possible to use as the non-woven fabric spunlace non-woven fabric, spunbond non-woven fabric, thermal bond non-woven fabric, air-through non-

woven fabric, point bond non-woven fabric, etc., spunbond non-woven fabric and thermal bond non-woven fabric are preferable. ~~The fibers forming the non woven fabric may be~~ any Any of natural fibers, synthetic fibers, and composite fibers may be used as the fibers to form the non-woven fabric. The basis weight of the non-woven fabric preferably ranges from approximately 20 g/m² to 100 g/m².
Of the base material sheet

Specification Page 13 - Amended with Underlining
And Strikethroughs

6, ~~the surface thereof to which the main cleaning portion~~
~~is bonded (which is the lower surface)~~ a lower surface
thereof bonded to the main cleaning portion may be
subjected to surface treatment, such as degreasing,
filling-up, or surface roughening.

As shown in Fig. 1, the base material sheet 6 may
have, in its peripheral edge portion, a plurality of strips
10 to form a ~~sub-cleaning~~ sub-cleaning portion. In this
embodiment, the plurality of strips 10 are provided on
either side of the handle mounting portion 2. The base
material sheet 6 does not necessarily consist of a single
sheet; it is also possible to form it by stacking together
two or more sheets. When forming the base material sheet 6
by stacking together a plurality of sheets, the sheets
stacked together are not necessarily of the same kind; it
is also possible to stack together sheets of different
materials, colors, etc.

The fiber bundle 7 is formed as a sheet consisting of
a large number of fibers bundled together, and a plurality
of fibers may be collected together to a degree that the
fibers do not become loose. However, the fiber bundle 7
may also be one in which the fibers are partially connected

together by heat sealing, adhesion, etc. as needed. The fiber bundle 7 can be obtained, for example, by a method in which a large number of sheet-like bundles of filaments are successively bonded together at appropriate intervals in a direction perpendicular to the longitudinal direction of the fibers, and then the intermediate portions between the bonded portions are cut.

Specification Page 14 - Amended with Underlining
And Strikethroughs

In the present invention, a filament refers to a single yarn continuous from the proximal to the distal end. The cleaning device of the present invention is characterized by the use of filaments in the main cleaning portion. This is in order to avoid the following problem: if the main cleaning portion were formed of staples, i.e., short fibers, there would be a fear of the staples, i.e., short fibers twisted together being worn and detached from the main cleaning portion as a result of the repeated use of the cleaning device. Thus, in the present invention, the term filament also covers a yarn formed by twisting together a plurality of filaments into a thick yarn; further, as long as it consists of a single continuous material, there are no particular limitations regarding the sectional dimension, configuration, etc. of the filament.

As the fibers forming the fiber bundle 7, it is possible to use, for example, natural fibers, such as cotton or wool, synthetic fibers, such as polyethylene, polypropylene, polyethylene terephthalate, nylon, or polyacrylic fiber, a composite fiber, such as a sheath-core fiber, an island fiber, or a side-by-side fiber, or the like. Of these, when connecting the fibers with each other

by heat sealing, it is desirable to use a sheath-core type composite fiber whose core consists of polypropylene and whose sheath consists of polyethylene. For, such a composite fiber exhibits both the superior fusibility of polyethylene forming the sheath and the firmness of polypropylene forming the core. Further, it is also

Specification Page 16 - Amended with Underlining
And Strikethroughs

diameter of the thick fibers, which is acceptable as long as it is larger than that of the thin fibers, preferably ranges from 0.06 mm to 0.3 mm. When stacking together a plurality of sheet-like fiber bundles differing in fiber thickness, fiber kind, color, etc., there are no particular limitations regarding the number of fiber bundles to be stacked together; usually, the number preferably ranges from 2 to 10.

There are no particular specific limitations regarding the fiber length; it generally ranges from approximately several centimeters to several tens of centimeters. The individual fibers may be of a uniform length or exhibit a variation.

The brush sheet 9, which can be formed, like the base material sheet 6, of paper, non-woven fabric, synthetic resin sheet, etc., is preferably formed of a synthetic resin sheet. Figs. 3A and 3B are plan views illustrating a method of producing the brush sheet 9. First, cutting is performed on an elongated sheet 11 along the longitudinal direction thereof to form a large number of cuts 12 such that cut-less portions 13 are intermittently provided ~~(Fig. 3A)~~ as shown in Fig. 3A. Then, the substantially central

portions of the cuts 12 are cut in the width direction of the sheet 11, thereby obtaining a plurality of brush sheets 9 in each of which there are a large number of bristle-like members 8 on either side of bristle-like-member-less portions 14 ~~(Fig. 3B)~~ as shown in Fig. 3B. It is desirable for the bristle-like members 8 to have a width larger than the diameter of the fibers forming the fiber

Specification Page 17 - Amended with Underlining
And Strikethroughs

bundle 7. ~~Examples of the synthetic resin sheet forming the brush sheet 9 include polyethylene and polypropylene~~
As the materials of the synthetic resin sheet for forming the brush sheet 9, polyethylene, polypropylene or the like are listed as examples. It is also possible to stack together a plurality of brush sheets 9.

In the cleaning device 1 of the present invention, the base material sheet 6 and the fiber bundle 7 are glued to each other at least in part, and are integrally bonded together. Further, at least a part of the bristle-like-member-less portion 14 of the brush sheet 9 is integrally bonded to the base material sheet 6 and the fiber bundle 7 by means of an adhesive. As the method of partially gluing the base material sheet 6, the fiber bundle 7, and the brush sheet 9 to each other, there is adopted, for example, a method in which, as shown in Fig. 4, adhesion is effected by an adhesive 15 linearly applied and an adhesive 16 applied in a spot-like fashion.

Examples of the adhesive that can be used include emulsion type adhesive, two component setting type adhesive, thermoplastic resin type adhesive, elastomer type adhesive, thermosetting resin type adhesive, instant

adhesion type adhesive, and hot melt type adhesive. Of these, a hot melt type adhesive is preferable in that it allows quick adhesion operation by heating and cooling thereof. Alternatively, a solution type or emulsion type thermoplastic adhesive ~~or~~ and an elastomer type adhesive are preferable in that they exhibit good permeability with respect to the fibers and provide a deep adhesive layer.

Of the base material sheet 6 and the fiber bundle 7, the adhesive

Specification Page 19 - Amended with Underlining
And Strikethroughs

The fiber direction refers to the longitudinal direction of the filaments 30. In the filament bundling body 31, the fibers are bundled in a state in which their directions are aligned. It should be noted, however, that the filament bundling body 31 does not exclude a construction in which a slight amount of other fibers are mingled so as to extend in a direction crossing the large number of filaments 30 forming the filament bundling body. Further, to achieve the object of the present invention, apart from extending in a straight line linearly to form the filament bundling body 31, the filaments 30 may also be bent entirely or locally. Thus, in the present invention, when it is said that the filaments 30 are aligned in the fiber direction, this is intended to preclude a state in which the fibers are oriented at random; that is, this is intended to mean that the general configurations and orientations of the filaments 30 are analogous to each other, without having to strictly coincide with each other in the fiber direction.

The large number of filaments 30 aligned in the fiber direction are first bundled with each other at the bundling portion to form the filament bundling body 31. There are

no particular limitations regarding the configuration of the filament bundling body 31; it may be, for example, of a planar, a straw-bag-like, or a block-like configuration. In bundling, the large number of filaments 30 are collected in a predetermined fiber density in the radial direction. In contrast, in the fiber direction, they may be collected while

Specification Page 20 - Amended with Underlining
And Strikethroughs

aligned at their one end or center, or collected in an irregular state.

There are no particular limitations regarding the means for bundling together the filaments 30 to obtain the filament bundling body 31, and it is possible to select a suitable means according to the material of the filaments 30. When the filaments 30 consist of a material with fusibility, heat sealing is suitable from the viewpoint of the number of processes and the processing time. ~~The~~ As the heating method, ~~may be~~ a heating/pressurizing system using a press heater, or an ultrasonic fusion system may be used. Apart from this, impregnation with adhesive or mutual binding of the filaments 30 by sewing is possible. Further, it is also possible to combine these methods with each other.

The material of the filaments 30 may be selected from the filament materials mentioned with reference to the first embodiment. Further, as the filaments 30, it is possible to use ones of the same material and the same degree of fineness (thickness), or a plurality of kinds mixed together. In particular, by combining fibers of different degrees of fineness with each other, it is

possible to achieve an improvement in terms of dust scraping-out performance, and to advantageously prevent entanglement of the fibers. When obtaining the filament bundling body 31 by bundling together filaments 30 of different kinds of material ~~by~~ with heat sealing, common materials are adopted, or materials whose melting points are close

Specification Page 21 - Amended with Underlining
And Strikethroughs

to each other are selected. ~~This is in order~~ These
purposes are to prevent thermal deterioration of the
material due to excessive heating during heat sealing and
to achieve an improvement in operational efficiency.

There are no particular limitations for the bundling
portion 40 constituting the bundling portion of the
filaments 30 regarding the place, configuration, and number
thereof. . For example, when connecting together the
filaments 30 impregnated with adhesive, the bundling
portion 40 has a predetermined width. In the case of
connection by heat sealing, the linear bundling portion 40
is generally provided in a direction crossing the
filaments. However, there is no need for all the filaments
30 constituting the filament bundling body 31 to be
integrally connected by one bundling portion 40; it is also
possible for the whole to be connected by two or more
bundling portions 40. That is, as long as all the
filaments 30 are connected with any of the other filaments
30 and not separated from the filament bundling body 31,
the bundling portion 40 may be, for example, of a
construction in which a plurality of short linear ~~segment-~~
~~like~~ bundling portions crossing the filaments 30 are

provided in a zigzag fashion.

Fig. 6 is an exploded perspective view of a cleaning device according to a second embodiment of the present invention. Reference numeral 6 indicates a base material sheet, reference numeral 20 indicates a main cleaning portion, and reference numeral 50 indicates an adhesive. A large number of filaments 30 aligned in the fiber

Specification Page 22 - Amended with Underlining
And Strikethroughs

direction and having fusibility are heat-sealed at a single band-like bundling portion 40 provided substantially at the center in the fiber direction, thereby forming a filament bundling body 31. This formation is effected prior to the bonding of the base material sheet 6 and the filament bundling body 31. For the base material sheet 6, a material as mentioned with reference to the first embodiment can be selected. Further, in the peripheral edge portion of the base material sheet 6, it is possible to provide a plurality of strips 10 to form a sub cleaning portion. Fig. 6 shows how a cleaning device according to the present invention is obtained by bonding the filament bundling body 31 to the base material sheet 6 by means of the adhesive 50 applied to the base material sheet 6 over a width W.

The cleaning device of the present invention can be used as a cleaning cloth for wiping off dust with the filaments 30 which condition becomes flat with respect to the base material sheet 6, or as a mop head with the forward ends of the filaments 30 bulged and fluffed out of the plane of the base material sheet 6, or as something in between with part of the filaments 30 fluffed. In any of

these cases, the cleaning device of the present invention is characterized in that dust is wiped off and caught by the main cleaning portion 20 formed by the filaments 30.

The filaments 30 are fixed to the cleaning device 1 by the bundling portion connecting the filaments to each other, and, in

Specification Page 24 - Amended with Underlining
And Strikethroughs

bundling portion 40 to first form the filament bundling body 31. Thereafter, at substantially the central portion with respect to the fiber direction, the filament bundling body 31 and the base material sheet 6 are bonded to each other by means of the adhesive 50 at a band-like bonding portion 51 with a width including the bundling portion 40. The movable portions of the filaments 30 form the main cleaning portion 20. By fluffing the main cleaning portion 20 outside the plane of the base material sheet 6, it is possible to obtain the mop-head-like cleaning device of this embodiment. Since the distal ends 21 can move around in a wide range, the cleaning device of this embodiment is capable of not only capturing dust on a flat surface or a convex surface but also scraping out dust in a groove and catching the same.

In the second and third embodiments described above, it is also desirable to place a brush sheet with a plurality of bristle-like members between the filament bundling body 31 and the base material sheet 6 and to integrally bond them to each other by means of an adhesive.

Here, description will be made on the advantage of a certain ~~predetermined~~ variation, between filaments 30 close

to each other, in the lengths and positions of the movable portions of the filaments 30, that is, the lengths from the fixed ends 22 to the distal ends 21 of the filaments 30 and the positional relationship thereof. When the lengths of the movable portions and the positions of the

Specification Page 25 - Amended with Underlining
And Strikethroughs

fixed ends 22 greatly differ between filaments 30 close to each other, the movable ranges of the distal ends 21 also greatly differ. Thus, the dust collection areas covered by the individual movable portions differ from each other, so that in the main cleaning portion 20 as a whole, the dust collection areas overlap each other, making it easy to obtain a dust collection performance free from spots.

Further, since the positions of the distal ends 21 of filaments 30 close to each other and their movable ranges greatly differ, it is advantageously easy to avoid a deterioration in the dust collection performance of the main cleaning portion 20 due to entanglement and conglomeration of the filaments 30.

There are several methods of achieving such effects. All of the following methods, which have been described above, provide an effect of discontinuously varying the lengths and the positions of the filaments 30:

(A) the method in which a variation is previously imparted to the lengths of the filaments 30;

(B) the method in which when bundling the filaments 30 together to form the filament bundling body 31, the positions of the filaments 30 in the fiber directions are

made irregular; and

(C) the method in which the bundling portion 40 for bundling together the filaments 30 is formed by a plurality of short linear ~~segment-like~~ portions provided in a zigzag fashion.

Further, in the method of the present invention, in which the:

Specification Page 26 - Amended with Underlining
And Strikethroughs

filament bundling body 31 and the base material sheet 6 are bonded to each other by means of an adhesive, it is possible to obtain an effect of varying the lengths and the positions of the movable portions still more discontinuously. The filaments 30 contained in the filament bundling body 31 include filaments close to each other in the height direction (vertical direction) as from the base material sheet 6 and in the in-plane direction (lateral direction) of the base material sheet 6.

Of these, description will be made first on the principle underlying the fact that the lengths and the positions of the movable portions formed at the ends of filaments close to each other in the vertical direction greatly differ in some cases in the bonding system using an adhesive. The liquid adhesive applied between the base material sheet and the filament bundling body permeates in the height direction from the base material sheet through the gaps between the filaments to a certain ~~predetermined~~ height (depth) by capillary action. It should be noted, however, that a slight difference not only in the application thickness of the adhesive but also in the local density of the filaments and the wettability of the fiber

surfaces leads to a difference in the permeation depth, with the result that the adhesion pattern of the filaments becomes inevitably complicated.

As a specific example, Fig. 8 ~~gives~~ shows a schematic sectional view of the adhesion bonding portion between the base material sheet

Specification Page 27 - Amended with Underlining
And Strikethroughs

6 and the filament bundling body 31 taken along the fiber direction of the filaments. Reference numeral 21 indicates representative distal ends of filaments, reference numeral 22 indicates fixed ends, reference symbols L1 and L2 indicate permeation depths of the adhesive 50, reference numerals 211 through 213 indicate distal ends at different depth positions, and reference numerals 221 through 223 indicate the corresponding fixed ends at these depths. The sections between their respective fixed ends and distal ends constitute movable portions 201 through 203. Due to its permeability, the adhesive 50 applied to the base material sheet 6 permeates through the gaps of the filaments to a predetermined depth. Thus, not only are the uppermost filaments in direct contact with the base material sheet 6 but also the filaments existing within the predetermined depth are glued and bonded to the base material sheet 6 by the adhesive 50, so that the fixed end positions of these filaments are relatively close to the distal ends thereof (as in the case of the fixed ends 221, 222). As a result, the lengths of the movable portions are small (as in the case of the movable portions 201, 202). On the other hand, the filaments which are at depth

positions to which the adhesive 50 does not permeate are connected to the base material sheet 6 solely through the intermediation of the bundling portion 40, so that the fixed end positions of these filaments are near the central portions thereof (as in the case of the fixed end 223), and the lengths of the movable portions of these filaments are

Specification Page 28 - Amended with Underlining
And Strikethroughs

relatively large (as in the case of the movable portion 203). Further, as shown in Fig. 8, the movable portions 201 and 202 adjacent to each other in the height direction (vertical direction) as from the base material sheet 6 greatly differ in their lengths due to the permeation spot of the adhesive 50.

Described next will be the principle underlying the fact that, in the bonding system using an adhesive, the lengths and positions of filaments close to each other in the in-plane direction (lateral direction) of the base material sheet 6 differ greatly in some cases. In bonding the base material sheet and the filament bundling body to each other by means of an adhesive, the shape and area in which the adhesive is applied are arbitrary, and it is possible to effect bonding at a plurality of spotted positions.

For example, as shown in the perspective view of Fig. 9, it is also possible to glue and bond the base material sheet 6 and the filament bundling body 31 to each other by a plurality of spot-like bonding portions 51. In the drawing, the upper side is the surface bonded to the lower surface of the base material sheet 6 (not shown), and the

lower side is the dust collecting surface. Further, representative movable portions constituting the main cleaning portion 20 are indicated by thick lines.

As shown in the drawings, through dispersed arrangement of the spot-like bonding portions 51 at a plurality of positions in the substantially central portion with respect to the fiber direction

Specification Page 33 - Amended with Underlining
And Strikethroughs

material sheet 6. Further, it is easier to visually recognize the contour line of the handle mounting portions 2 and, by extension, the positions of the insertion holes 3, whereby the operation of mounting the handle 4 is facilitated. There are no particular limitations regarding the coloring agent for coloring the adhesive 50; it is possible to suitably use pigments, such as natural mineral pigment, inorganic synthetic pigment, insoluble organic pigment, and lake pigment, or dyes, such as natural dye, synthetic dye, and fluorescent dye.

In this way, apart from the bonding of the main cleaning portion 20 to the lower surface of the base material sheet 6, and the formation of a sub cleaning portion through provision of strips in the peripheral edge portion of the base material sheet 6 itself, it is desirable to perform various kinds of processing also on the upper surface thereof to thereby achieve an improvement in terms of usability as a cleaning device. In the conventional system in which the fibers and the base material sheet are integrally bonded together by heat sealing, a convex press mark is generated on the upper surface of the base material sheet, which is liable to

impair the workability ~~machinability~~ of the same. In contrast, in a system in which, as in the present invention, the fiber bundle and the base material sheet are bonded together, there is no need to apply excessive heat and pressure in the bonding process, so that the above problem is eliminated, and the bonding of the handle mounting portions 2, for

Specification Page 35 - Amended with Underlining
And Strikethroughs

In the fifth step or the sixth step, in order to bond the base material sheet 6 and the filament bundling body 31 to each other to a sufficient degree, it is also suitable, in addition to the heating and pressurization of the whole by the heater roll, to further heat and pressurize a predetermined portion alone by means of a hot cutter.

For example, as shown in Fig. 6, the filament bundling body 31 formed by bundling together a large number of filaments by fusion at the substantially central portion in the fiber direction, is crushed thin in the vicinity of the bundling portion 40. Thus, when stacking the filament bundling body 31 together with the base material sheet 6, the bundling portion 40 of the filament bundling body 31 is not in close contact with the lower surface of the base material sheet 6, generating a gap 52 at this position (Fig. 11).

~~When, in~~ In applying a hot melt type adhesive between the filament bundling body 31 and the base material sheet 6 in order to bond them to each other, when the adhesive is applied in an amount larger than usual, both components are reliably bonded together, providing a predetermined adhesion strength. When, however, the application amount

of adhesive remains a usual amount, the above-mentioned gap 52 is not sufficiently filled with adhesive, and there is a fear of the adhesion strength where the filament bundling body 31 is bonded to the base material sheet 6 at the bundling portion 40 being rather insufficient. In the latter case, it is desirable to press,

And Strikethroughs

bundling body 31 and the base material sheet 6 being cured or a press mark remaining on the upper surface of the base material sheet 6; further, the production efficiency for the cleaning device is not markedly deteriorated.

According to the present invention, the bonding of the fiber bundle 7 and the base material sheet 6 can be effected reliably and efficiently. That is, in the case in which the fiber bundle 7 composed of fibers with fusibility and the base material sheet 6 formed of non-woven fabric are used, when the bonding of the fiber bundle 7 to the non-woven fabric is to be executed by heat sealing alone, the hot cutter applied to the fiber bundle 7 first melts the fibers by heating, and then the heat is conducted to the non-woven fabric to melt the non-woven fabric by heating. However, the non-woven fabric is a fiber entanglement body, and its surface exhibits surface irregularities, so that it is rather difficult for the heat to be conducted uniformly. In addition, the non-woven fabric has a void texture, so that its heat transfer ~~conduction~~ efficiency is low. Thus, the fiber bundle 7, which is in uniform contact with the hot cutter, is quickly heated and melted, whereas it is rather difficult to

integrally fuse the fiber bundle 7 and the non-woven fabric even when the non-wove fabric is formed of fibers which are of the same material and have the same diameter as the fibers forming the fiber bundle 7.

As a result, in the conventional technique, in which the base
